- Nondeterministic Turing Machine

# Deterministic Turing Machine

- In order to formalize the notion of an algorithm, we will need to fix a particular model for computation.
- One of them is the deterministic one-tape Turing machine (DTM for short). It consists of
  - a finite state control,
  - a read-write head, and
  - a tape made up of a two-way infinite sequence of table square, labeled  $\dots, -2, -1, 0, 1, 2, 3, \dots$

# A Program for a DTM

A program for a DTM specifies the following information:

- (1) A finite set  $\Gamma$  of tape symbols, including a subset  $\Sigma \subset \Gamma$  of input symbols and a distinguished blank  $b \in \Gamma - \Sigma$ ;
- (2) State set  $Q$ , initial state  $q_0$ , halt states  $q_y$  and  $q_n$ ; and
- (3) Transition function  $\delta: (Q - \{q_y, q_n\}) \rightarrow Q \times \Gamma \times \{l, r\}$ .

The operation of such a program is straightforward. The *input* to the DTM is a string  $x \in \Sigma^*$ . The string  $x$  is placed in tape squares 1 through  $|x|$ , one symbol per square.

# DTM

- All other squares initially contain the blank symbol.
- The program starts its operation in state  $q_0$ , with the read-write head scanning tape square 1.
- The computation then proceeds in a step-by-step manner.
- If the current state  $q$  is either  $q_y$  or  $q_n$ , then the computation has ended, with the answer being 'yes' if  $q = q_y$  and 'no' if  $q = q_n$ .
- Otherwise, the current state  $q$  belongs to  $Q - \{q_y, q_n\}$ , some symbol  $s \in \Gamma$  is in the tape square being scanned, the value if  $\delta(q, s)$  is defined.

# DTM

## Example

$$Q = \{q_0, q_1, q_2, q_3, q_r, q_N\}$$

$$\Gamma = \{0, 1, b\}, \Sigma = \{0, 1\}$$

$$\begin{aligned} \delta: & (q_0, 0) \rightarrow (q_0, r); (q_0, 1) \rightarrow (q_0, r); (q_0, b) \rightarrow (q_1, l); \\ & (q_1, 0) \rightarrow (q_2, b); (q_1, 1) \rightarrow (q_3, b); (q_1, b) \rightarrow (q_n, b); \\ & (q_2, 0) \rightarrow (q_y, b); (q_2, 1) \rightarrow (q_n, b); (q_2, b) \rightarrow (q_2, l); \\ & (q_3, 0) \rightarrow (q_n, b); (q_3, 1) \rightarrow (q_n, b); (q_3, b) \rightarrow (q_3, l). \end{aligned}$$

# DTM

On the input  $x = 10100$ , we have the following computation:

# DTM

# DTM

- The above example illustrates the computation of a simple DTM  $M$  on an input  $x = 10100$ , giving the state, head position, and the contents of the non-blank portion of the tape before and after each step.
- Note that this computation halts after six steps, in state  $q_y$ , so the answer for 10100 is ‘yes’.
- In general, we say that a DTM program  $M$  with input alphabet  $\Sigma$  accepts  $x \in \Sigma^*$  if and only if  $M$  halts in state  $q_y$  when applied to input  $x$ . The language  $L_M$  is given by

$$L_M = \{x \in \Sigma^* : M \text{ accepts } x\}.$$

# DTM

For an input  $x \in \Sigma^*$ , there are three possibilities:

- (1)  $M$  accepts  $x$ , halting at state  $q_y$ .
- (2)  $M$  does not accept  $x$ , halting at state  $q_n$ .
- (3)  $M$  continues forever without halting.

For a DTM program to correspond to the concept of an algorithm, it must halt on all possible strings over its input alphabet.

*P-class of problem:*

$P \equiv \{L \subset \{0, 1\}^* \mid L \text{ can be accepted by a } M \text{ in polynomial time. } \}$

# NDTM

## Nondeterministic Turing Machine - NDTM

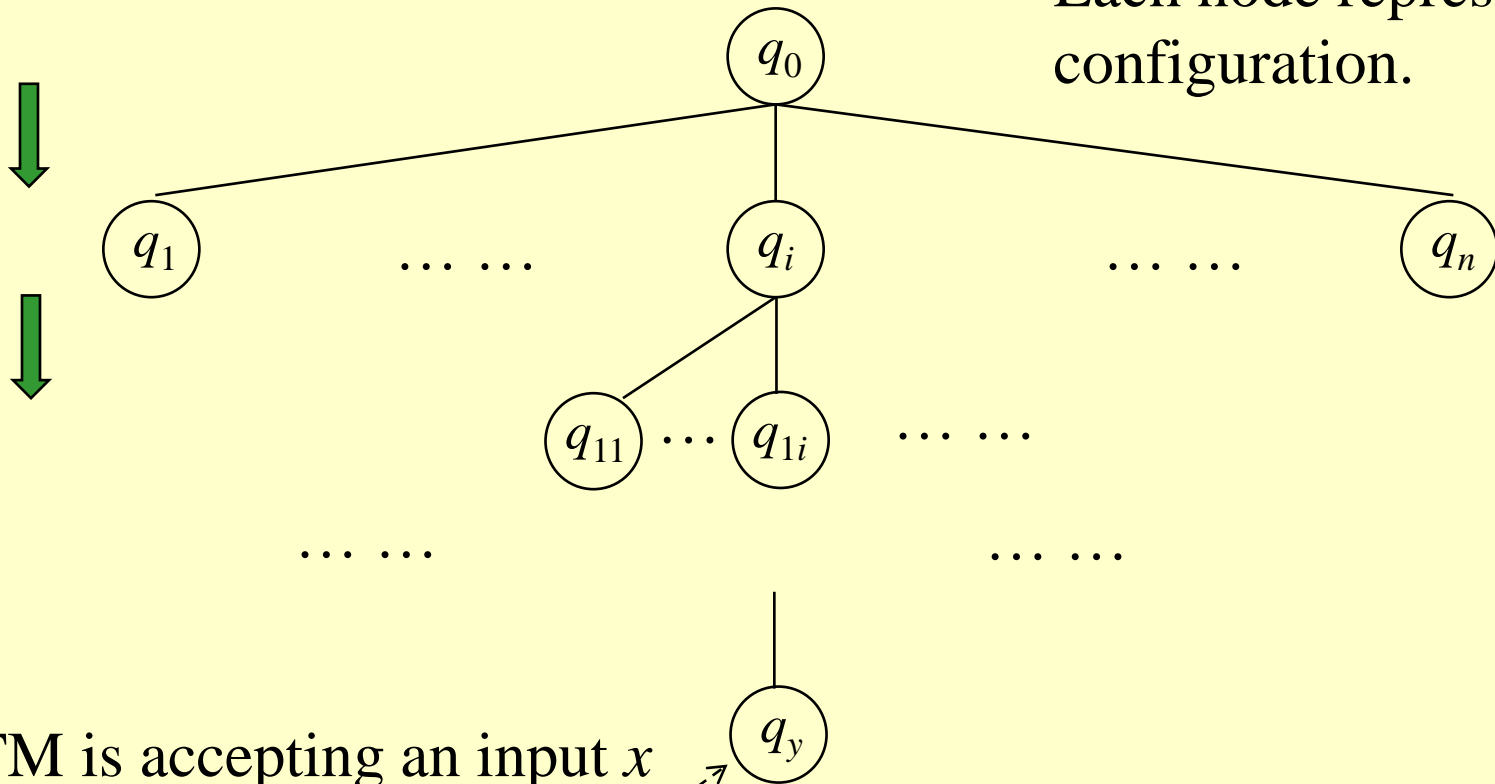

A program for a NDTM specifies the following information:

- (1) A finite set  $\Gamma$  of tape symbols, including a subset  $\Sigma \subset \Gamma$  of input symbols and a distinguished blank  $b \in \Gamma - \Sigma$ ;
- (2) State set  $Q$ , initial state  $q_0$ , halt states  $q_r$  and  $q_N$ ; and
- (3) Transition function  $\delta: (Q - \{q_y, q_n\}) \rightarrow Q \times \Gamma \times \{l, r\}$ .
- (4) At any state, the machine can be transferred from a configuration to multiple successor configurations.

# NDTM

The computation of NDTM on an input  $x$  can be illustrated as an tree of size exponential in  $|x|$ .

Each node represents a configuration.

NDTM is accepting an input  $x$  iff some sequence of choices goes to  $q_y$ .

# NDTM

*NP-class of problem:*

$NP \equiv \{L \subset \{0, 1\}^* \mid L \text{ can be accepted by an } NDTM \text{ in polynomial time.}\}$
